

CM/LM publication map

One existing manuscript, two prospective mathematical papers

18 September 2026 *Priority remains conditional; models stay explicit.*

Paper B — Boolean operator computation

Central thesis: Typed operand metadata admits sound operator fusion before operand evaluation; value is determined by matched total cost, not a unique truth-table identity. **Primary cluster:** CM-B-001–007 and CMP-001–006: contraction, signed-frame fusion, LM pairing, compiler paths and exploratory S1/S2 evidence. **Imported background:** Boolean matrix/vector logic, truth tables, cut/LUT/NPN methods, ANF and sharing-aware evaluation. **Remaining work:** Update exploratory results now; freeze and run natural workload timing/memory with strong comparators before positive performance claims. **Strongest risk:** Generic two-support optimization matches all seven recorded work metrics in the 10,389 fully admitted synthetic cases. **Relationship:** Foundational manuscript; later papers cite its results. No separate folding paper now.

P01 — Contextuality and exact information resources over finite chain rings

Central thesis: Under specified complete-basis and invertible-orbit contracts, Smith support and leading multiplicity classify contextuality and give the exact dh codebook; teleportation demands stronger invertibility. **Primary cluster:** MOD-003–005; RES-001–004; tensor/operation boundaries MOD-001/009/010; two-setting boundary MOD-007. **Imported background:** Paper B, finite-chain-ring modules, MQT, possibilistic global sections and elementary span/rank facts. Rotation and the chosen LM enrichment are supporting exposition, not independent novelty. **Remaining work:** Theorem-level priority comparison and independent proof review; optional odd-residue/mixed-characteristic support CSP certificates. **Strongest risk:** Antecedented classification/orbit results, or hidden primitivity/operation assumptions. Display the nonprimitive maximal separator and primitive dimension-three contrast. **Relationship:** Draft first. Owns resource theory and the short enriched symbolic-support interface; no separate bridge article now.

P02 — Exact query obstructions in characteristic-two modal computation

Central thesis: Exact complete linear readout gives Deutsch = 2, DJ one-query obstruction and $BV = n$ under the stated oracle contract; genuine kickback need not yield an invertible character analyzer. **Primary cluster:** ALG-002–005, with direct-sum discrimination, phase/interface details and the known UNIQUE-SAT positive control supporting. **Imported background:** Polynomial-query methods, finite-field/semiring computation, reversible oracle embeddings, standard character algebra. **Remaining work:** Dedicated exact-contract priority review and full adaptive-record proof review. Matching upper bounds use standard XOR, not arbitrary coincident oracle gates. **Strongest risk:** A known or routine modal-query specialization; convert to a focused note or supplement if the central novelty disappears. **Relationship:** Draft second; imports only required algebra from P01 and does not duplicate its resource-classification proofs.

Deferred: Standalone rotation, LM bridge and folding articles; a broad laboratory/software paper needs a later distinct usability/reproducibility center. No physical quantum realization or closed unrestricted process theory is claimed. Drafts can start now; priority and performance gates remain real.
